UNIVERSITÄT BONN

Sequence Processing

Moritz Wolter

September 29, 2022

High-Performance Computing and Analytics Lab, Uni Bonn

Overview

Motivation

- Thus far we have never integrated information over time.
- We want the ability to create internal memory.
- Consider the sentence: I live in Paris. I speak ...
- ... French.
- Clearly it is likely for someone in Paris to speak French.
- Memory should help networks taking Paris into account when deciding what language is spoken.

Recurrent neural networks

Motivation

- Recurrent neural networks are often considered the goto choice for sequences.
- Chapter ten in [GBC16], for example, bears the title "Sequence Modeling: Recurrent and Recursive Nets".

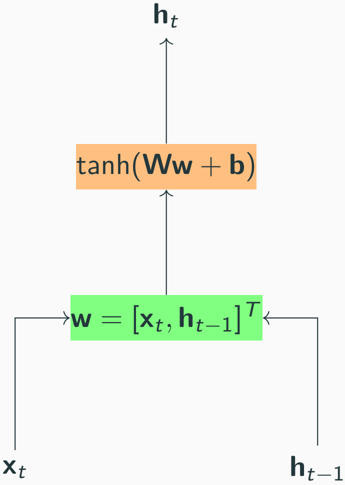
Elman-recurrent neural networks

A simple solution is to add a state to the network and feed this state recurrently back into the network [Elm90],

$$\overline{\mathbf{h}_t} = \mathbf{W}_h \mathbf{h}_t + \mathbf{W}_x \mathbf{x}_t + \mathbf{b}, \tag{1}$$

$$\mathbf{h}_{t+1} = f(\overline{\mathbf{h}_t}). \tag{2}$$

Elman-recurrent neural networks



Unrolling in Time

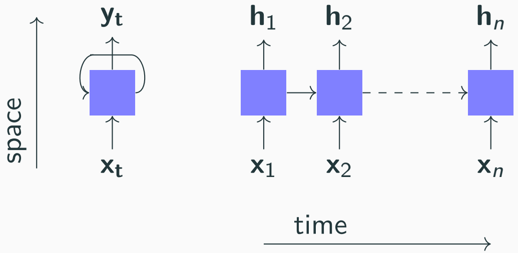


Figure: The rolled (left) cell can be unrolled (right) by considering all inputs it saw during the current gradient computation iteration.

Stability of recurrent connections

For an intuition. Consider a linear network without activations or inputs.

$$\mathbf{h}_{t+1} = \mathbf{W}_h \mathbf{h}_t \tag{3}$$

The evolution of the **h**-sequence is guided by it's largest eigenvalue. If an eigenvalue larger than one exists. The state explodes. If all eigenvalues are smaller than one the state vanishes [GBC16].

Long Short Term Memory (LSTM)

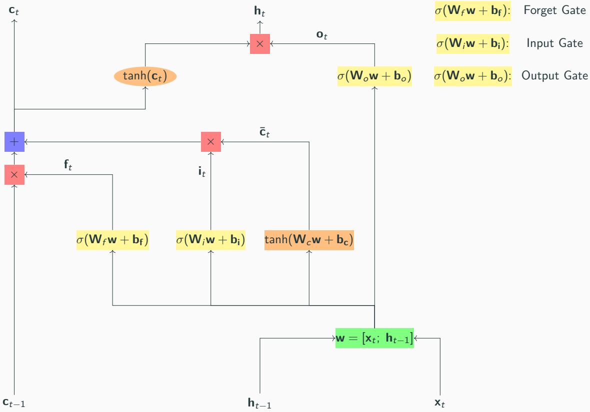

Figure: An LSTM cell as described in[HS97; Gre+16].

Long Short Term Memory (LSTM)

Llike a differentiable memory chip [Gra12] LSTM-memory can store n_h numbers. Gates govern all changes to the cell state. Gate and state equations are defined as [HS97; Gre+16]

$$\mathbf{z}_t = \tanh(\mathbf{W}_z\mathbf{x}_t + \mathbf{R}_z\mathbf{h}_{t-1} + \mathbf{b}_z), , \tag{4}$$

$$\mathbf{i}_t = \sigma(\mathbf{W}_i\mathbf{x}_t + \mathbf{R}_i\mathbf{h}_{t-1} + \mathbf{p}_i \odot \mathbf{c}_{t-1} + \mathbf{b}_i), \tag{5}$$

$$\mathbf{f}_t = \sigma(\mathbf{W}_f\mathbf{x}_t + \mathbf{R}_f\mathbf{h}_{t-1} + \mathbf{p}_f \odot \mathbf{c}_{t-1} + \mathbf{b}_f), \tag{6}$$

$$\mathbf{c}_t = \mathbf{z}_t \odot \mathbf{i}_t + \mathbf{c}_{t-1} \odot \mathbf{f}_t, \tag{7}$$

$$\mathbf{o}_t = \sigma(\mathbf{W}_o\mathbf{x}_t + \mathbf{R}_o\mathbf{h}_{t-1} + \mathbf{p}_o \odot \mathbf{c}_t + \mathbf{b}_o), \tag{8}$$

$$\mathbf{h}_t = \tanh(\mathbf{c}_t) \odot \mathbf{o}_t. \tag{9}$$

Potential new states $\mathbf{z}_t$ are called block input. $\mathbf{i}$ is called the input gate. The forget gate is $\mathbf{f}$ and $\mathbf{o}$ denotes the output gate. $\mathbf{p} \in \mathbb{R}^{n_h}$ are peephole weights, $\mathbf{W} \in \mathbb{R}^{n_i \times n_h}$ denotes input, $\mathbf{R} \in \mathbb{R}^{n_o \times n_h}$ are the recurrent matrices. $\odot$ indicates element-wise products.

Long Short Term Memory (LSTM)

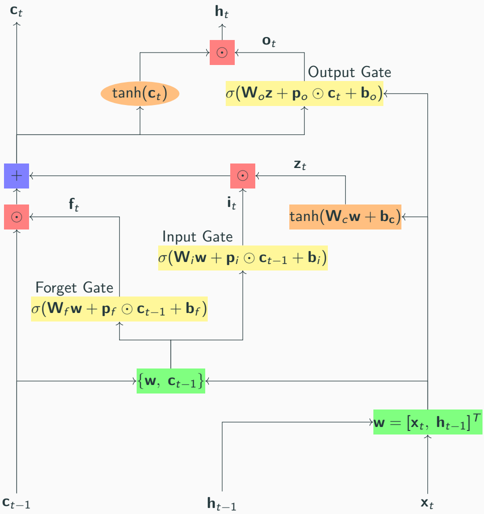

Figure: An LSTM-cell with peephole connections as described in [HS97; Gre+16]

Gated recurrent Units

$$\mathbf{r}_t = \sigma(\mathbf{W}_r \mathbf{h}_{t-1} + \mathbf{V}_r \mathbf{x}_t + \mathbf{b}_r), \tag{10}$$

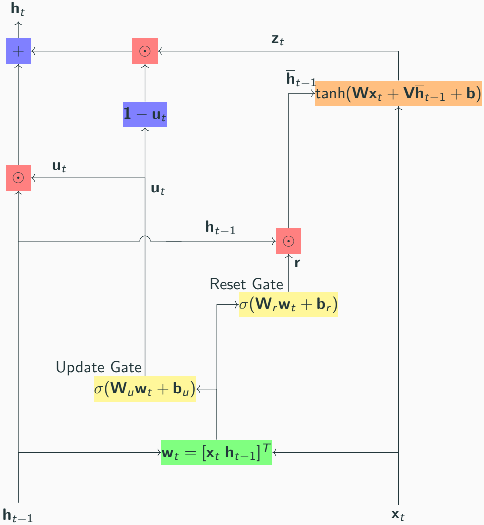
$$\mathbf{u}_t = \sigma(\mathbf{W}_u \mathbf{h}_{t-1} + \mathbf{V}_u \mathbf{x}_t + \mathbf{b}_u) \tag{11}$$

$$\mathbf{z}_t = \tanh(\mathbf{W}(\mathbf{r}_t \odot \mathbf{h}_{t-1}) + \mathbf{V}\mathbf{x}_t + \mathbf{b}), \tag{12}$$

$$\mathbf{h}_t = \mathbf{u}_t \odot \mathbf{z}_t + (1 - \mathbf{u}_t) \odot \mathbf{h}_{t-1}. \tag{13}$$

$\mathbf{h}_t \in \mathbb{R}^{n_h}$ denotes the cell state and output at time t. The block input is called $\mathbf{z}_t \in \mathbb{R}^{n_h}$. The reset $\mathbf{r} \in \mathbb{R}^{n_h}$ and update gates $\mathbf{u} \in \mathbb{R}^{n_h}$ take care of memory management. $\mathbf{W} \in \mathbb{R}^{n_i \times n_h}$ denote input matrices, $\mathbf{V} \in \mathbb{R}^{n_h \times n_h}$ is used for recurrent weight matrices.

Gated recurrent units



Stiefel Manifold Weight Updates [Wisdom2016]

$$\mathbf{h}_t = \mathrm{ReLU}(\mathbf{W}_h \mathbf{h}_t + \mathbf{W}_x \mathbf{x}_t + \mathbf{b}) \tag{14}$$

$$\mathbf{W}_{k+1} = (\mathbf{I} + \frac{\lambda}{2}\mathbf{A}_k)^{-1}(\mathbf{I} - \frac{\lambda}{2}\mathbf{A}_k)\mathbf{W}_k, \tag{15}$$

$$\text{where} \qquad \mathbf{A} = \mathbf{W}\overline{\nabla_{\mathbf{w}} F}^T - \overline{\mathbf{W}}^T \nabla_{\mathbf{w}} F. \tag{16}$$

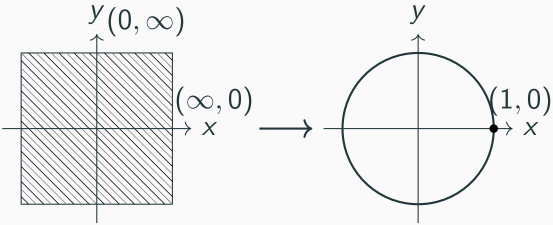


Figure: Fix the optimized matrix eigenvalues onto the unit circle.

Summary

- LSTM works like a differentiable memory chip.
- When in doubt, use LSTM.

Applications

One hot encoding for letters. A possible encoding looks for all characters in a dataset. The number of occurring characters determines the length of every one-hot character vector. A system that accepts text and produces text, therefore, maps one-hot encoded sequences onto each other.

Example: Machine Translation

[BCB15] used RNN for the task of machine translation.

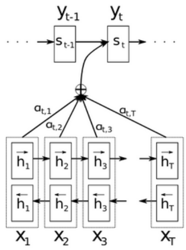

Figure 1: The graphical illustration of the proposed model trying to generate the t-th target word y_t given a source sentence $(x_1, x_2, \ldots, x_T)$.

Figure: An RNN-based translation system. Figure from [BCB15].

Neural attention in machine translation

Attention weights group related inputs together, allowing a decoder to find a suitable translation.

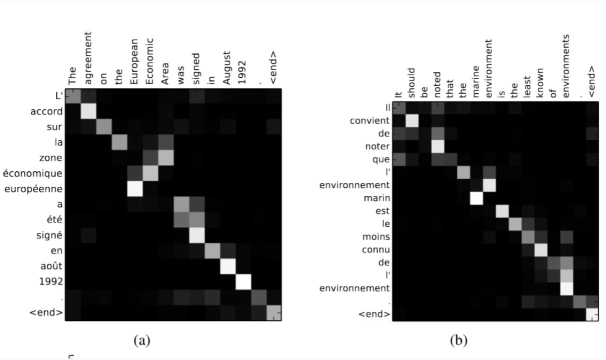

Figure: Attention plots as observed in [BCB15].

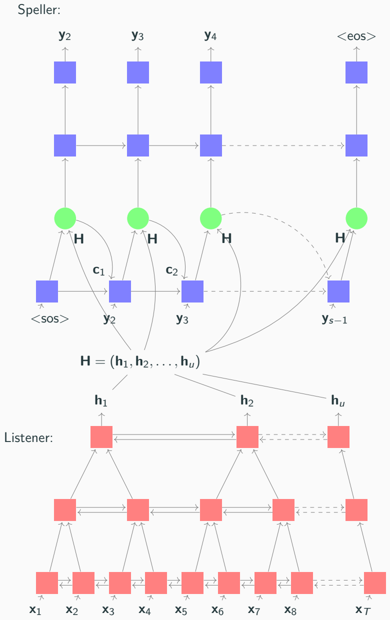
Neural Keyboard

Given a sequence of input letters or words LSTM, for example, can model the probability of the next letter or word.

$$p_n(y_i|y_1, y_2, \ldots, y_{i-1} = LSTM(y_{i-1}, c_{i-1}, h_{i-1}) \qquad (17)$$

This could, for example, help users type.

Speech Processing [Cha+15]



Time-series forecasting

Conclusion

- RNNs are versatile and suitable for many different sentence processing tasks.
- Let's explore a generative Language modeling example today.
